1 Introduction

In this assignment we investigate the behaviour of different types of methods such as Direct solvers, Jacobi's method and preconditioned conjugate convergence method, using Cholesky factorization for defining preconditioners. We look at the convergence properties of the residuals as well as the time dependence with respect to different accuracy conditions. Lastly we use what we have discovered in early exercises to construct an efficient solver for the heat equation in a two-dimensional plate.

2 Problems

2.1 Direct solvers

Table 1: Table showing variables for increasing N

N	M ²	nnz(A)	nnz(L)	time	timeSolve
10	81	369	737	1.06e-02	4.32e-04

The N at which the $\text{nnz}(L)$ exceeds $\text{nnz}(A)$ by a factor of 10 is $N = 60$, and the N at which the factorization time exceeds 1 second is $N = 260$. It is clearly visible in Table 1 that the time for computing the Cholesky factorization is increasing dramatically for increasing N .

2.2 Jacobi's method

In the first task of this part, we are asked to plot the residual history for a solver that uses Jacobi's method. This is shown in Figure 1 below. It is clear that the method converges.

Figure 1: Residual history for Jacobi's method.

To convince ourselves that the method converges linearly however, we want

$$\lim_{i \rightarrow \infty} \frac{\|res_{i+1}\|}{\|res_i\|} = C,$$

where $0 < C < 1$. Hence, we plot this quote for sufficiently many iterations, and see that we indeed get a convergence towards approximately 0.8. This is shown in Figure 2, and the conclusion is that the method has linear convergence.

Figure 2: Shows that the method converges linearly, since the quote plotted converges towards a finite value.

Further, to show that the method is independent of N , we try and plot the logarithm of the residual history divided by N . The result of doing this is shown in Figure 3 below, and it is clear that the lines we look at are parallel to each other. This implies that the method is indeed independent of N .

Figure 3: Plot of the residual history divided by the size of their systems. Shows the N independence of Jacobi's method.

2.3 CG-method with no preconditioner

When testing the conjugate gradient method without preconditioner, we can conclude that it needs more than one second to converge when the size of the system corresponds to $N = 1440$. The code for this test is given in the appendix and is named `testCG.m`.

3 CG-algorithm with preconditioning

In this exercise we test how CG algorithms depends on their preconditioners, and start of by varying N , λ, τ and tol . The tables given in Section 3.1 below was generated.

3.2 Time plots

Further, we wanted to see how the time consumption of the CG process depends on the drop tolerance τ , and so plots shown in Figure 4 to 9 shows the factorisation time, solve time and the sum of these two separately versus the drop tolerance.

Figure 4: N=100

Figure 5: N=200

Figure 6: N=300

Figure 7: N=400

Figure 8: N=500

Figure 9: N=600

From the plots, it is obvious that the choice of drop tolerance has an impact on the time consumption, since it has a clear minimum at $\tau = 10^{-3}$ for all N .

4 Solution of the heat equation for a two dimensional plate

In this part we want to modify `heatSim.m` in order to make it faster and finish with a solution in less than 12 seconds. This is done by implementing preconditioned conjugate gradient method using Matlabs built-in `pcg()`. We use an incomplete Cholesky factorization to construct a preconditioner for `pcg`, and in this a drop tolerance of $\tau = 10^{-3}$ since this proved to be efficient in previous exercise. This resulted in a computation time of 10.6 seconds on my Macbook pro, which should mean that it should be able to run even faster on a cs-computer. The plot given in Figure 10 shows a representation of the solution at the final time step.

Figure 10: Solution of heat equation plotted after the simulation is done.

5 Conclusion

From doing the experiments in this laboration, there are some conclusions that can be drawn from the results. First we saw that the time consumption for performing Cholesky factorization to further solve a system using its components, increases quite dramatically with increasing system size. Then we ran some tests on Jacobi's method and saw that it had linear convergence rate and that the method is independent of its size N , in regards to its residual history. Further we looked at both preconditioned and non-preconditioned conjugate gradient method and saw that the choice of drop tolerance had an impact on the time consumption of the method. Finally we use the knoweledge gain from previous exercises to make a solver for the heat equation more efficient. We could conclude that a preconditioner made a huge impact in optimising the solver when using conjugate gradient method.
